

MARVIN: reasoning over a billion triples

What's a triple?

What are lots of triples?

How much is one billion?

Let's say this is one triple

[Vrandečić, 2007]

This

Suez: 10^7 triples
(10 million)

The moon: 10^8 triples

The earth: 10^9 triples
(1 billion)

[Vrandecic, 2007]

Jupiter: 10^{10} triples
(1 triple per webpage)

[Vrandečić, 2007]

We need to scale

We need to scale what?

We need to scale reasoning

What is reasoning?

- Amsterdam is a city
- All cities are big
 - Thus, Amsterdam is big

Reasoning is: combining pieces of data

MaRVIN

- 1) we have many compute nodes
- 2) each gets piece of data
- 3) does all reasoning on that data
- 4) swaps some data with other nodes
- 5) and goes back to 2)

What's hard about MARVIN?

- not all combinations of data are useful
(Amsterdam is a City & all Dogs are Animals)
- randomly exchanging data is inefficient
- centralised coordination expensive
- want: decentralised, efficient, and loadbalance

Let's experiment ...

- Random: each triple sent to random peer
- DHT: each triple sent to responsible peer, based on hashcode of triple (push)
- SpeedDating: each peer gets triples closest to the area he's responsible for (pull)

Let's see some animations

- Random
- DHT
- SpeedDating

Summary

- billions of triples is a lot
- reasoning over them is not trivial
- we invent & experiment with distribution
- see <http://larkc.eu/marvin>
